

# Why Kotlin?

A short introduction to the Kotlin language

Antonis Lilis

Mobile Engineer @ ADVANTAGE

FINANCIAL SYSTEMS EXPERTS

**Learn Kotlin in 45'**

# **Why Kotlin?**

# Some History

- **2010:** JetBrains starts developing Kotlin
- **2011:** JetBrains **unveiled** Project Kotlin, a new language for the JVM
- **2012:** JetBrains **open sourced** the project under the Apache 2 license
- **2016:** Kotlin **v1.0** is released
  
- **2017:** Kotlin support in **Spring** Framework
- **2017:** Google announced **first-class support for Kotlin on Android**
  
- Kotlin is **technically 8**, but in reality **2 years old**

# The Kotlin Language

- **Statically Typed**
  - Type validation at compile time
- Supports **Type Inference**
  - Type automatically determined from the context
- Both **Object Oriented** and **Functional**
- **First-class functions**
  - You can store them in variables, pass them as parameters, or return them from other functions
- Was designed with **Java Interoperability** in mind

# Constants and Variables

- **val** (from value)
  - **Immutable** reference
- **var** (from variable)
  - **Mutable** reference
- **Nullable** Types
  - Defined **Explicitly**

```
val someInt: Int = 42
var someString = "forty-two"
var someValue: Int? = 23
```

No  
semicolon  
here ;)

```
someInt = 23 //It is constant
someString = "twenty-three"
someString = 5 //It is a String
someString = null //Cannot be null
someValue = null
```

# Control Flow

- Classic loops:
  - **if**
  - **for**
  - **while / do-while**
- **when**
  - Replaces the switch operator
  - No breaks, no errors

```
when (x) {  
    1 -> print("x == 1")  
    2 -> print("x == 2")  
    else -> { //block  
        print("not 1 or 2")  
    }  
}
```

# Functions

- **Named** arguments
- Can be declared at the **top level** of a file (without belonging to a class)
- Can be **Nested**
- Can have a **block or expression body**

```
fun max(a: Int, b: Int): Int { //name – parameters – return type  
    return if(a>b) a else b //function block body  
}
```

```
fun max(a: Int, b: Int) = if(a>b) a else b //expression body
```

```
max(a = 1, b = 2) //call with named arguments  
max( a: 1, b: 2)
```

# Functions

- **Default** parameter values
  - No method overloading and boilerplate code

```
fun doSomethingWith(letter: Char, number: Int = 42) {  
    val res = "The letter is ${letter} and the number is $number"  
    println(res)  
}
```

```
doSomethingWith(letter = 'C', number = 1)
```

```
doSomethingWith(letter = 'A')
```

```
doSomethingWith( letter: 'A')
```

Simple string  
Interpolation

# Classes

```
class MyView : View {  
    constructor(ctx: Context): super(ctx) {  
        //Initialization stuff  
    }  
    //...  
}
```

```
class MyViewShort(ctx: Context) : View(ctx) {  
    //...  
}
```

```
class Car(val brand: String, val isUsed: Boolean = false)  
  
val car = Car(brand: "Ford")
```

**data classes:**  
autogenerated  
implementations of  
universal **methods**  
(equals, hashCode  
etc)

```
data class Bike(val brand: String, val isUsed: Boolean = false)
```

# Modifiers

- **Access** modifiers
  - **final** (default)
  - **open**
  - **abstract**
- **Visibility** modifiers
  - **public** (default)
  - **internal**
  - **protected**
  - **private**

***"Design and document for inheritance  
or else prohibit it"***

*Joshua J. Bloch, Effective Java*

*ps. Lukas Lechner has written a series of articles on  
"How Effective Java influenced Kotlin" (<http://lukle.at>)*

# Properties

- **first-class** language feature
- combination of the **field**  
and its **accessors**

```
class House {  
  
    var street: String = "Ermou"  
    var number: String = "1"  
    var city: String = "Athens"  
  
    var state: String? = null  
  
    var zip: String = ""  
    set(value) {  
        state = "TK.$value"  
    }  
  
    val prettyAddress: String  
    get() = "$street $number, $city"  
  
}
```

# No static keyword

- **Top-level** functions and properties  
(e.g. for utility classes)
- **Companion objects**
- The **object** keyword:  
declaring a class and creating an instance  
combined (**Singleton**)

```
class Foo {  
    companion object {  
        fun bar() {  
            //...  
        }  
    }  
}
```

```
object Singleton {  
    fun doSomething() {  
        //..  
    }  
}
```

Foo.bar()

Singleton.doSomething()

# Extensions

- Enable **adding methods and properties** to other people's classes
  - Of Course without access to private or protected members of the class

```
fun String.lastChar(): Char  
    = this.get(this.length - 1)
```

```
val String.lastChar: Char  
    get() = get(length - 1)
```

```
val last: Char = "hi".lastChar()
```

```
"hello".lastChar
```

# Null Checks

- Safe-call operator ?.
- The **let** function
- Elvis operator ?:

```
fun strLen(s: String?): Int? = s?.length
```

```
fun strLen(s: String?): Int = s?.length ?: 0
```

```
fun sendEmailTo(email: String) { }
```

```
var email: String? = "yole@example.com"  
email?.let { sendEmailTo(it) }
```

```
email = null  
email?.let { sendEmailTo(it) } //won't be executed
```

***"I call it my billion-dollar mistake.  
It was the invention of the null reference in 1965"***

*Tony Hoare*

# Not-null assertion operator !!

```
fun rootOfAllEvils(s: String?) {  
    val sNotNull: String = s!!  
    println(sNotNull.length)  
}
```

# Safe Casting

- Safe cast operator **as?**
- Smart cast
  - combining type checks and casts

```
var myview: MyView? = MyView(ctx)
val view = myview as? View

if (view is MyView) {
    view.bar()
}
```

# Lamdas and Higher Order Functions

```
val sum = { x: Int, y: Int -> x + y }
```

```
val sum: (Int, Int) -> Int = { x, y -> x + y }
```

```
println(sum(1, 2))
```

```
fun twoAndThree(operation: (Int, Int) -> Int) {  
    val result = operation(2, 3)  
    println("The result is $result")  
}
```

```
twoAndThree(operation = {a, b -> a + b})  
twoAndThree { a, b -> a * b }
```

# Collections

- Kotlin **enhances** the **Java** collection classes (**List**, **Set**, **Map**)

```
class Car(val brand: String, val age: Int, val horsepower: Int)
```

```
val fleet = listOf(  
    Car( brand: "Ford",   age: 1,   horsepower: 100),  
    Car( brand: "Mazda",  age: 2,   horsepower: 120),  
    Car( brand: "Opel",   age: 2,   horsepower: 95))
```

```
fleet.maxBy { it.horsePower }
```

```
fleet.filter { it.age == 2 }
```

```
fleet.filter { it.age == 2 }.maxBy { it.horsePower }
```

```
fleet.forEach { print("brand: $it.brand") }
```

Chained  
Calls

# Delegation

- **Composition over Inheritance** design pattern
- **Native support** for delegation (implicit delegation)
- **Zero Boilerplate** code
- Supports both **Class Delegation** and **Delegated Properties**

Class Car **inherits from an interface** Nameable and **delegates** all of its public **methods to a** delegate **object** defined with the **by keyword**

```
interface Nameable {  
    var name: String  
}  
  
class Ford : Nameable {  
    override var name = "Ford"  
}  
  
class Car(name: Nameable)  
    : Nameable by name  
  
val car = Car(Ford())  
print(car.name) //Ford
```

# Domain-specific language construction

- Kotlin provides mechanisms for creating internal DSLs that use exactly the **same syntax** as all language features and are fully **statically typed**

```
object start

infix fun String.should(x: start)
    = StartWrapper( value: this)

class StartWrapper(val value: String) {
    infix fun with(prefix: String)
        = value.startsWith(prefix)
}

"kotlin".should(start).with( prefix: "kot")

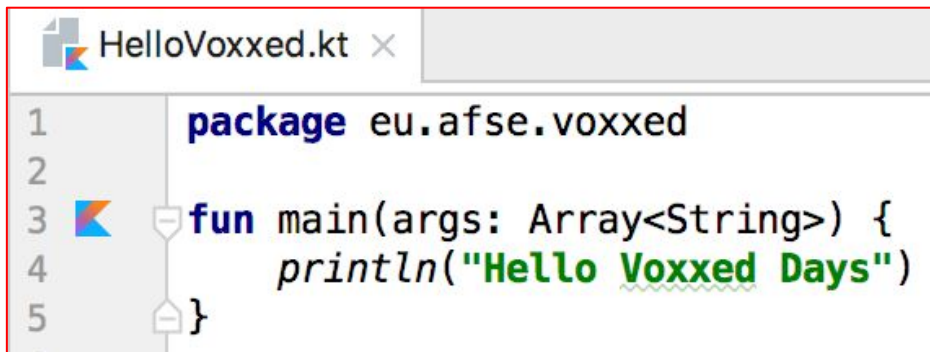

"kotlin" should start with "kot"
```

```
table { this: TABLE
    tr { this: TR
        td { this: TD
            + "Cell A"
        }
        td { this: TD
            + "Cell B"
        }
    }
}
```

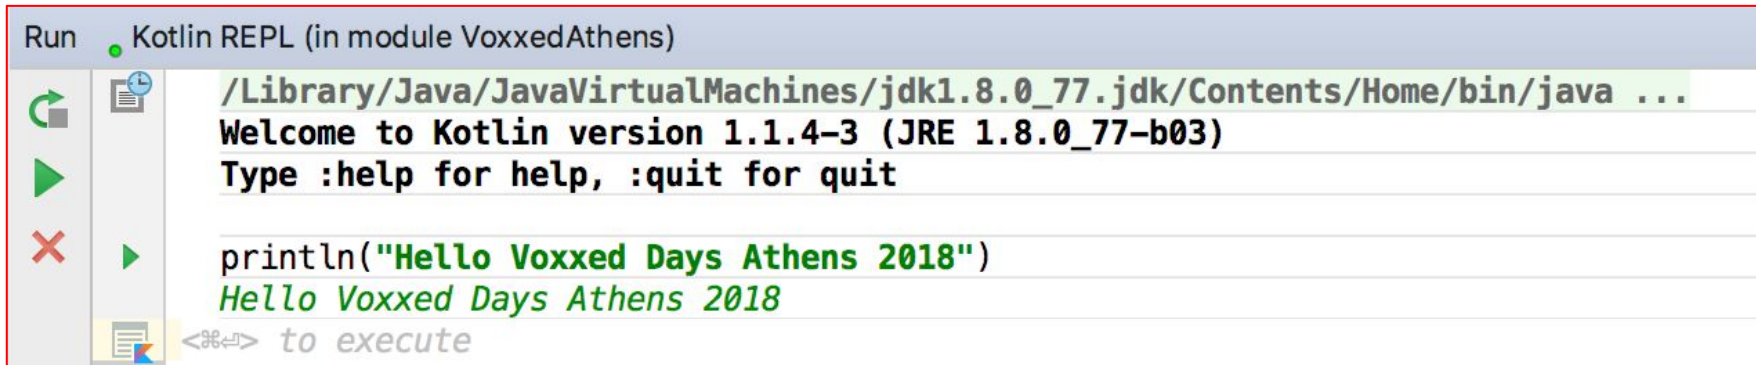

# Hello World

- Kotlin files have **.kt extension**
- You can also try your code in **REPL** (Read-Eval-Print-Loop)

```
1 package eu.afse.voxxed
2
3 fun main(args: Array<String>) {
4     println("Hello Voxxed Days")
5 }
```

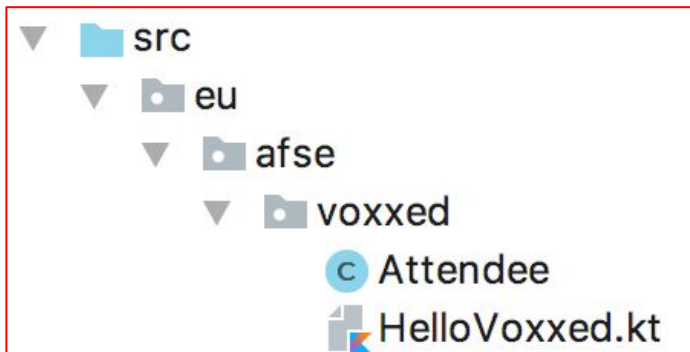

Run Kotlin REPL (in module VoxxedAthens)

```
/Library/Java/JavaVirtualMachines/jdk1.8.0_77.jdk/Contents/Home/bin/java ...
Welcome to Kotlin version 1.1.4-3 (JRE 1.8.0_77-b03)
Type :help for help, :quit for quit

println("Hello Voxxed Days Athens 2018")
Hello Voxxed Days Athens 2018

<=> to execute
```

# Let's Mix with some Java

```
package eu.afse.voxxed;
```

```
public class Attendee {
```

```
    private String email;
```

```
    private String name;
```

```
    public Attendee(String email, String name) {
```

```
        this.email = email;
```

```
        this.name = name;
```

```
    }
```

```
    public String getName() {
```

```
        return name;
```

```
    }
```

```
}
```

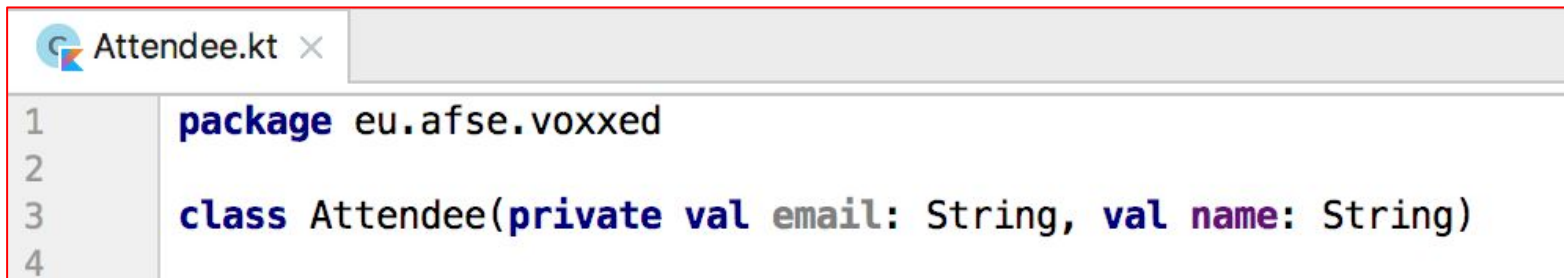

# Java from Kotlin

- You can call Java code from you Kotlin files transparently

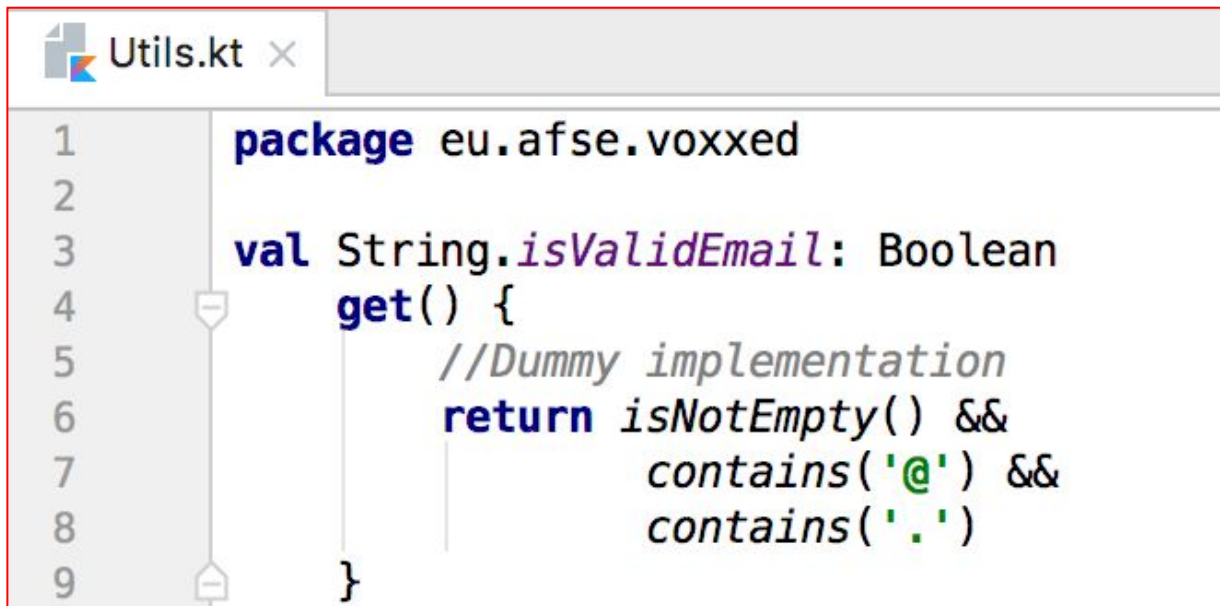

```
1 package eu.afse.voxxed
2
3 fun main(args: Array<String>) {
4
5     val attendee = Attendee( email: "antonis.lilis@gmail.com", name: "Antonis")
6
7     println("Hello ${attendee.name}")
8 }
```

# Convert Java to Kotlin

# Utility

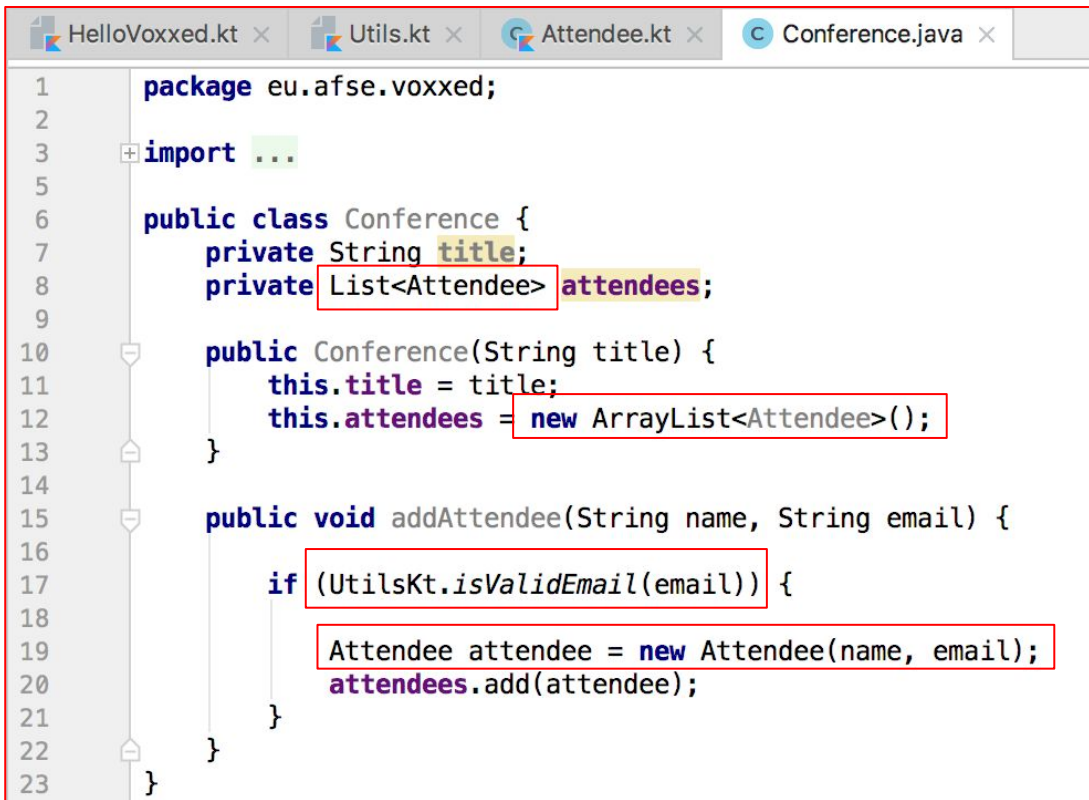

- **Top-level** computed **property**
- String **extension**

```
1 package eu.afse.voxxed
2
3 val String.isValidEmail: Boolean
4     get() {
5         //Dummy implementation
6         return isEmpty() &&
7             contains('@') &&
8             contains('.')
9     }
```

# Kotlin from Java

- In most cases the integration is **Seamless**
- Some **Kotlin features do not exist in Java** (e.g. top level functions or properties)
- In such cases **conventions** are used
- In our case a **static class is generated** for the **top-level declarations**

```
1 package eu.afse.voxxed;
2
3 import ...
4
5
6 public class Conference {
7     private String title;
8     private List<Attendee> attendees;
9
10    public Conference(String title) {
11        this.title = title;
12        this.attendees = new ArrayList<Attendee>();
13    }
14
15    public void addAttendee(String name, String email) {
16
17        if (UtilsKt.isValidEmail(email)) {
18
19            Attendee attendee = new Attendee(name, email);
20            attendees.add(attendee);
21        }
22    }
23 }
```

The screenshot shows an IDE with four tabs: HelloVoxxed.kt, Utils.kt, Attendee.kt, and Conference.java. The main editor displays the contents of Conference.java, which is a Java file containing Kotlin-style code. The code defines a `Conference` class with two private fields: `String title` and `List<Attendee> attendees`. The `attendees` field is highlighted with a red box. The class has a constructor `Conference(String title)` that initializes `this.title` and `this.attendees` with `new ArrayList<Attendee>()`. There is also a `addAttendee(String name, String email)` method. Inside this method, there is an `if` statement checking `UtilsKt.isValidEmail(email)`, which is also highlighted with a red box. If the email is valid, a new `Attendee` object is created with `new Attendee(name, email)` and added to the `attendees` list. The `Attendee` class is imported from `eu.afse.voxxed`.

# Libraries & Resources

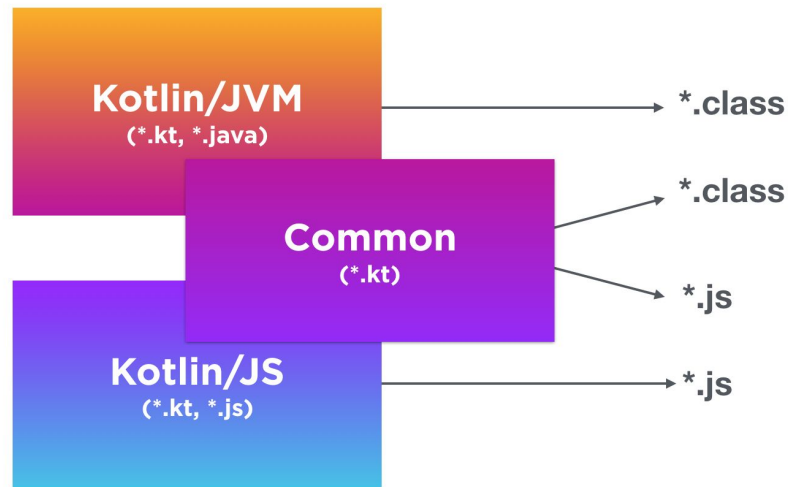

- The Kotlin **standard library** is great
- You can use **Any Java Library** since Java and Kotlin are 100% interoperable
- **Kotlin libraries:** a nice curated list at <https://kotlin.link>
- Kotlin **popularity is growing** and resources become more abundant

[REF: [Jetbrains Kotlin blog](#)]

# Kotlin also lives outside the JVM

- Kotlin 1.1 (March 2017): officially released the **JavaScript** target, allowing you to compile Kotlin code to JS and to run it in your browser
- Kotlin 1.2 (November 2017): adding the possibility to **reuse code** between the JVM and JavaScript
- Kotlin/**Native** v0.6 (Valentine's Day 2018): Better support for native targets (e.g. **iOS**, **WebAssembly**, **Windows**)

[REF: [Jetbrains Kotlin blog](#)]

# Any Disadvantages?

- An app built with Kotlin will likely result in a **larger file** package size than one built purely in Java (and a bigger method count)
- The **build time** for Kotlin is sometimes a little slower

# Name shadowing

- Probably a design flaw
- Produces an warning in IDEA

```
fun xShadow(x : Int) {  
    val x = 1 //Java: already defined error  
    if (x == 0) {  
        val x = 2 //Java: already defined error  
    }  
    println ("x = $x")  
}  
xShadow(3)  
x = 1
```

# Null Safety vs Java Interoperability

```
public class Utils {  
    public static String format(String text) {  
        return text.isEmpty() ? null : text;  
    }  
}
```

```
@Test fun testFormat1() {  
    //Platform type String! (String or String?)  
    val f = Utils.format( text: "" )  
    assertNull(f)  
}  
  
@Test fun testFormat2() {  
    val f: String = Utils.format( text: "" ) ?: ""  
    assertNotNull(f)  
}  
  
@Test fun testFormat3() {  
    val f: String? = Utils.format( text: "" )  
    assertNull(f)  
}  
  
@Test fun testFormat4() {  
    val f: String = Utils.format( text: "" )!!  
    assertNotNull(f)  
}
```

**In my** 

# My World

## Objective-C

```
- (NSString*) joinAString:(NSString*) stringParam andAnInteger:(int) intParam {  
    return [NSString stringWithFormat:@"%s%d", stringParam, intParam];  
}  
  
[self joinAString:@"Voxxed" andAnInteger:2018];
```

## Swift

```
func join(aString: String, anInteger: Int) -> String {  
    return "\(aString)\(anInteger)"  
}  
  
self.join(aString: "Voxxed", anInteger: 2018)
```

## Kotlin

```
fun join(aString: String, anInteger: Int): String {  
    return "$aString$anInteger"  
}  
  
this.join(aString = "Voxxed", anInteger = 2018)
```

}  
Similar  
Syntax

# Met Java in 2000

- Freshman in the university
- The only language I knew was Basic (not the Visual one)

# Java was Cool

- Java was new and exciting
- Java was creating new developer communities
- Developers coming from C++ and other languages were happy

```
int num = 5;  
int *x = &num;
```

```
int **y = &x;
```

# Hardcore Devs

- C++ Devs talked about
  - the superior performance
  - How powerful C++ is
- Java Developers
  - They did not care
  - The code was easier to write
  - Maintainable
  - Safer: No manual memory management
  - Happy developers

# Two decades later

- I feel that kotlin is like Java
- It is new, cool and it solves problems

# Why Kotlin?

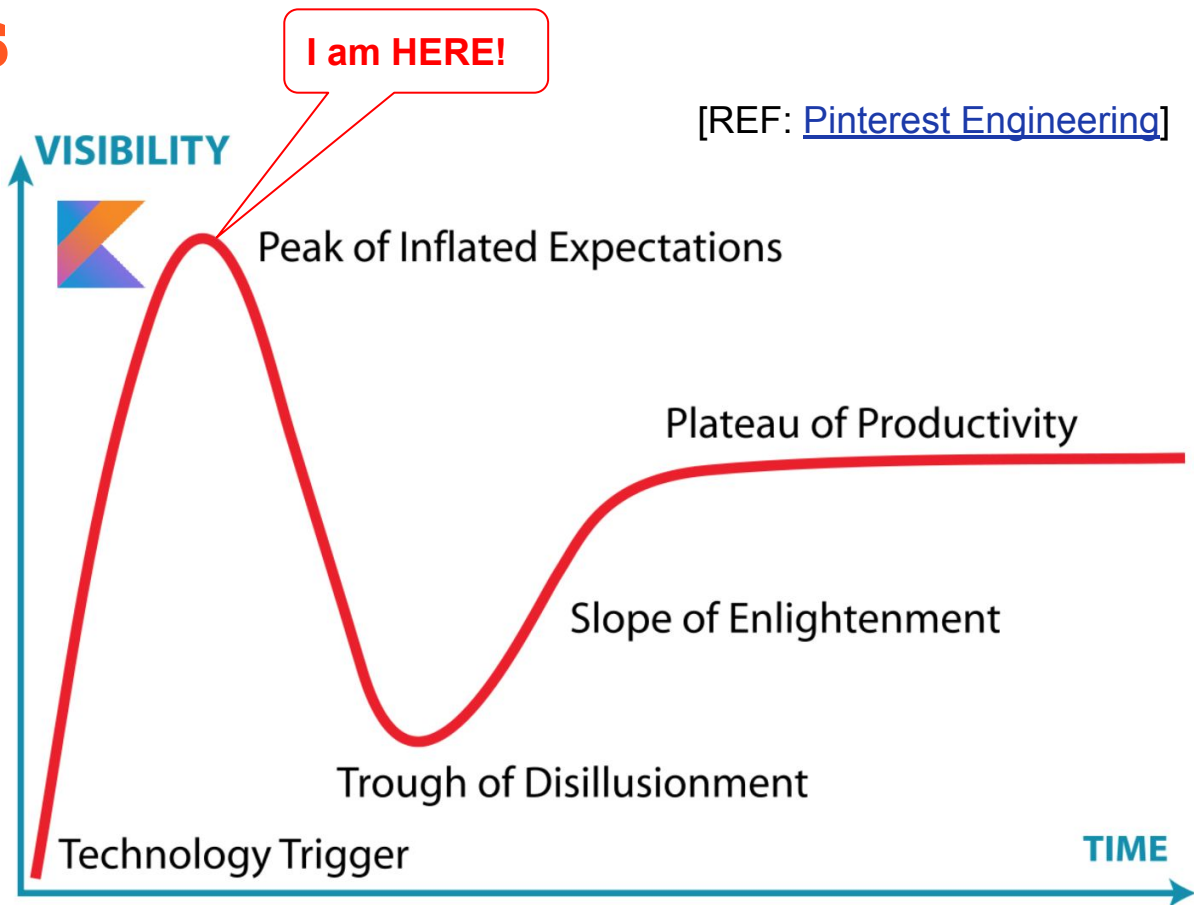

1. Makes **writing code** easier
2. Has incremental **learning curve**
3. Has nice **features**
4. Follows modern **programming language trends**
5. Can be easily **mixed with Java**
6. Suitable for **incremental adoption**
7. On **Android** there is no way back
8. Is designed by **Jetbrains** that makes some of the best developer tools
9. Is **supported** by major vendors (**Google**, Spring etc)
10. Kotlin has a **growing community**

# Final Thoughts

- **Not so popular yet**
  - 49th in [TIOBE Index](#) for May
  - Competed with C for language of the year 2017
  - Growing fast in [PYPL Popularity Index](#) (16th)
- **Development Stability**
  - Tools still in **Beta**
  - **Static Analysis** Tools
- **Reversibility**

**IMHO** Kotlin is here to stay

**Thank you!**

**Questions?**
